## INTRODUCTION

(This page intentionally left blank)

## Transportation Modeling

The TransAction Plan uses the transportation network modeled by MWCOG TPB, and applies a more detailed TRANSIMS simulation to more accurately represent the flow of vehicles. The model used for TransAction builds upon the TRANSIMS-based modeling tools developed as part of the 2015-2016 and 2017 HB 599 project evaluation efforts by VDOT.

The HB599 model system was updated with two major changes: 1) incorporation of enhancements to evaluate transit and multimodal projects, and 2) update of the underlying network to include 2016 CLRP changes, and update of the travel demand to include Round 9 of the Cooperative Land Use Forecast. As part of the revision to the regional demand, an early version of the 2016 TPB/COG regional travel model inputs was obtained from MWCOG and run using other inputs from the latest regionally adopted version of the model - Version 2.3.57a.

An overview of the modeling process is shown in Figure A-2. Note that the TransAction TRANSIMS model works with travel information derived directly from the MWCOG/TPB model.

Figure A-1: Overview of the Modeling Process

The TRANSIMS model is developed at two geographies: at the MWCOG Regional level, and at the Northern Virginia level (NoVA). As shown in Figure A-3, the NoVA modeling boundary includes areas beyond the jurisdictions of NVTA, including downtown D.C. and the I-95 corridor through Fredericksburg, to improve the capture of complete trips in the TransAction model.

Figure A-2: NVTA TRANSIMS Regional Multimodal Network

The resulting travel times are used in the initial TRANSIMS mode choice application for the NoVA model area. The mode choice results are assigned to the NoVA network using a dynamic user-equilibrium for multimodal paths by minimizing the generalized cost (impedance) while also adjusting tolls on dynamically priced facilities to maintain minimum operating speeds and
for Northern Virginia
adjusting the parking and transit penalties by time of day to constrain demand to appropriate capacity levels.

The Northern Virginia network, specific to TransAction, is shown in Figure A-4.

## 1 Overview

### 1.1 Background

HB 2313 (2013), Virginia's landmark transportation funding legislation, provides the Northern Virginia Transportation Authority (NVTA) with a dedicated, sustainable funding stream to address the Northern Virginia region's transportation challenges.

It has been the NVTA's practice to update TransAction every five years in order to identify and prioritize regionally significant transportation improvements that can help reduce the effects of congestion throughout Northern Virginia. The current update of the TransAction Plan builds on the vision and goals developed for previous TransAction plans to develop a comprehensive long range transportation plan that reduces congestion and improves the quality of life in Northern Virginia.

However, the current update is under a higher level of scrutiny because this TransAction Update will guide NVTA's first Six-Year Program for allocating the HB2313 funding.

NVTA is working closely with VDOT to ensure that the evaluation processes conducted as part of TransAction and under the new HB 2313 legislation are compatible with the HB 599 legislation that has been used since 2014 to evaluate and prioritize projects for state and regional funding.

More information about NVTA's TransAction can be found at: http://nvtatransaction.org/
This document presents an overview of the modeling tool being used for TransAction. The tool is an enhancement of the regional model used for the HB 599 evaluation process. It uses the MWCOG forecasts and highway and transit networks, and adds detail related to dynamic movement of people and traffic through the network.

The summaries of model validation outputs presented below demonstrate that the model represents existing conditions and predicts future conditions with a level of accuracy that is appropriate for the TransAction planning process and subsequent NVTA Six-Year Program process.

Figure 1 shows the jurisdictions included in the NVTA region and significant roadways and transit routes.

Figure 1: NVTA Jurisdictions (Source: nvtatransaction.org)

### 1.2 Review Meetings with Peer Group

The transportation model used as the basis for TransAction was refined based on a focused peer review effort. The model outputs presented in this document reflect changes based on the peer review comments, along with further enhancements based on observations of early rounds of TransAction forecasting applications.

In developing the HB 599 modeling and analysis process, VDOT actively engaged a large group of local agencies including WMATA, MWCOG, and VRE, and an independent peer review panel of national experts to review and comment on the modeling methods and analysis techniques.
The TransAction modeling process builds on this work by calibrating and validating an expanded modeling process to 2016 conditions. The TransAction model was vetted through two model review meetings held with NVTA staff and VDOT's Northern Virginia modeler's group ${ }^{1}$. The first meeting was held in October 2016 and covered an overview of the TransAction modeling approach and preliminary model validation results. It was attended by representatives from the following:

- VDOT
- Prince William County
- Fairfax County
- NVTC
- MWCOG
- NVTA
- Loudoun County
- Arlington County
- AECOM

The second review meeting was held in November 2016 and was focused on updated model validation results based on the group's feedback from the first meeting. It was attended by representatives from the following:

- VDOT
- Fairfax County
- NVTC
- NVTA
- AECOM

[^0]Prior to the first meeting, a draft version of this report containing preliminary validation results was provided to the group. During the meeting, the presentation included the following topics:

1. Trip- and link- gaps showing model closure by time-of-day
2. Modeled trips at the MWCOG region level and at the Northern Virginia subregional level
3. Comparison of daily modeled volumes against the 2010 MWCOG counts
4. Daily Potomac River crossings, modeled vs. counts
5. Locations and levels of "worst" congestion of AM / PM peak period
6. Side by side comparison of modeled speeds against typical speeds ${ }^{2}$ reported on Google Maps at various times on a typical weekday.
7. Comparisons of all-day hourly speed profiles on several key facilities in the region, between INRIX data and modeled speeds.
8. Comparisons of daily Metrorail ridership by station, against 2014 LineLoad $^{3}$ and the COG model.
9. Comparisons of daily VRE ridership by station, against 2014 VRE survey and the COG model.

Overall, the group thought the model generated reasonable results. They found the conceptual maps that depict the worst congestion on network links through peak travel periods showed appropriate levels of congestion as perceived by travelers. The group made several valuable observations and provided many key inputs which are summarized below:

1. The group found the temporal patterns in the model to be reasonable, especially given the comparisons of the modeled and observed speeds at high and low speed levels. They also acknowledged the modeling challenge in reproducing congestion in a region such as ours with complex operations. For example, they observed that the model cannot be expected to fully reproduce diurnal distribution curves at 15-minute speed profiles for all trip origins and destinations.
2. The model-generated volumes on the American Legion Bridge were noted to be too low. Since this bridge is an external station for the Northern Virginia model, the regional assignment required improvement to generate realistic volumes on the bridge.
3. A remark was made regarding the 10 percent transit mode-share estimate for Northern Virginia. It was considered high given MWCOG's regional run with all unfunded projects had yielded only 9 percent mode share for the whole region. The
${ }^{2}$ Google Maps ${ }^{\circledR}$ provides an option to show "Typical Traffic" for different days of the week and different times of the day, based on patterns in historical "live" traffic speed data. More information is available at https://support.google.com/maps/answer/3092439?source=qsearch\&hl=en
${ }^{3}$ LineLoad is a tool utilized by WMATA in their planning department to estimate loads on Metro trains at various times of day. It utilizes mezzanine-to-mezzanine observed passenger entries and exits, and provides detailed ridership information for current and future years.
modeling team suggested that the difference in geographic scale should not be ignored as the transit share in Northern Virginia is higher than the region as a whole due to higher transit service levels and greater development density. It is also important to note that the Northern Virginia model includes downtown D.C.
4. The group thought that the modeled congestion levels on Route 28 in Manassas were lower than reality.
5. The group cautioned against excessive emphasis on observed data because in their experience data are limited to particular days, may suffer from quality issues, and does not always match observation given day-to-day variations in traffic levels. An example was provided regarding Typical Traffic on Google Maps which did not always match their experience, such as lower than observed congestion on I-95 inbound near the Capital Beltway in the AM peak period. Another example was given where the counts on the American Legion Bridge were shown to vary as much as 10 percent from day to day, hence an exact match to the observed ground count was not required. In a similar context, it was also mentioned that a recently published "HOV study report" ${ }^{4}$ suggested the percentage of carpool violators constitute approximately 36 percent of the total traffic on I-66 during restricted hours.
6. While VRE assignments seemed reasonable, some segments in the Metrorail assignments were found to be higher than observed.
7. The group offered to help review the network coding in their respective jurisdictions.

The feedback regarding network reviews and American Legion Bridge volumes proved to be most helpful. Loudoun County and Prince William County provided several targeted refinements to the network coding that were incorporated immediately by the modeling team. The investigation into the low American Legion Bridge volumes was traced to a process issue that had excluded internal-external trips (totaling approximately 900,000 trips or five percent of the regional demand) from the model during import of demand into the TransAction model from the MWCOG model. This issue was specific to the TransAction modeling and did not affect the original HB599 modeling. After the internal-external trips were included, refinements were also made to the speeds and capacities of the roadways adjoining the American Legion Bridge to account for the grade and vertical and horizontal curvatures that affect driver behavior. Furthermore, the transit and parking capacity constraints were reviewed in an attempt to improve the Metrorail and VRE assignments.

The results from the revised model were then presented at the second review meeting. The presentation outlined the actions taken and the corresponding results for all issues raised in the first meeting. Diurnal 15-minute volume profiles for I-66 and several parallel roadways compared modeled volumes to recent counts derived from VDOT's HOV study report. Maps were presented showing the dynamic park-and-ride utilization of rail parking lots in the study area. Additional comparison locations were provided near Manassas and along Route 28 to test observed versus modeled traffic levels.

[^1]The group found the model calibration/validation to have improved and to be a very reasonable basis for TransAction analysis. The group wanted assurances that the targeted changes to the base year (such as the speed/capacity adjustments near the American Legion Bridge, etc.) were being carried forward to the future year networks. All such changes were carried forward in all model applications. The group also suggested including several additional summaries in the model validation documentation - which have been included and referenced in this document. The results in this document also include further enhancements to the model, beyond the review meetings, based on continued interaction with the stakeholders and observations from preliminary forecasting applications.

### 1.3 Modeling

TransAction uses and builds upon the TRANSIMS-based modeling tools developed as part of HB599. A more detailed description of the modeling process can be found in the technical reports at http://www.virginiadot.org/projects/northernvirginia/evaluating significant projects.asp or directly at http://www.virginiadot.org/Final Report - v10.pdf.

The HB599 model system was updated with two major changes: 1) incorporation of enhancements to evaluate transit and multimodal projects, and 2) update of the underlying network to include 2016 CLRP changes, and update of the travel demand to include Round 9 of the Cooperative Land Use Forecast. As part of the revision to the regional demand, an early version of the 2016 TPB/COG regional travel model inputs was obtained from MWCOG and run using other inputs from the latest regionally adopted version of the model - Version 2.3.57a. An overview of the modeling process is shown in Figure 2.

Figure 2: Overview of the Modeling Process

As noticed in the modeling overview from Figure 2, the TRANSIMS assignments are performed at two geographies, i.e., at the Regional level and at the Northern Virginia level (NoVA). At the regional level, the assignments are performed with the TPB/COG mode shares, whereas the NoVA assignments are performed with TRANSIMS tour-based mode shares. The regional network and the NoVA modeling boundary (in orange) can be seen in Figure 3. The NoVA modeling boundary includes areas beyond the jurisdictions of NVTA, to include downtown D.C. and I-95 corridor through Fredericksburg, to improve the capture of complete trips in the NoVA model.

Figure 3: NVTA TRANSIMS Regional Multimodal Network

The demand for the regional assignment is derived from the TPB/COG regional travel model where the income stratification is preserved by rerunning the AEMS mode choice for individual
income strata. In addition, as a prior step, a CTPP-based trip distribution adjustment is performed to the home-based-work (HBW) person trips in order to improve the assignment of transit markets. The regional demand is converted to TRANSIMS format using ConvertTrips. As part of this process, the purpose-specific trips are retained in TRANSIMS tour-format by directly using the P-A format trip tables from the TPB/COG mode choice step to improve the handling of outbound and return trips in the TRANSIMS mode choice model. The NoVA assignment is initiated by including only the trips that pass through the NoVA model boundary. This includes all trips that are fully contained within this boundary and portions of trips that pass through the NoVA boundary. The NoVA assignments are initialized with the output of the regional assignment. The resulting travel times are used in the initial TRANSIMS mode choice application for the NoVA model area. The mode choice results are assigned to the NoVA network using a dynamic user-equilibrium for multimodal paths by minimizing the generalized cost (impedance) while also adjusting tolls on dynamically priced facilities to maintain minimum operating speeds and adjusting the parking and transit penalties by time of day to constrain demand to appropriate capacity levels.

The NoVA network can be seen in Figure 4. This figure has been adjusted to only show the area covered by the jurisdictions of NVTA. The roadway network can be seen in shades of grey. The local bus routes are shown in blue and the express bus routes are shown in green. The Metrorail and VRE are shown in red.

Figure 4: NVTA TRANSIMS Northern Virginia Multimodal Subregion Network

### 1.4 Mode Choice

Mode choice for the NoVA geography is performed using the TRANSIMS ModeChoice software with the nested logit model structure shown in Figure 5. Only the person-based, purposespecific tour skims from the NoVA assignment are modeled in ModeChoice. Miscellaneous vehicle trips converted from the MWCOG model are not modified.

Figure 5: TRANSIMS Mode Choice Structure

The mode choice calibration was performed with targets compiled for the HB599 work and adjusted to 14 regional travel markets derived from 7 geographic areas ("super districts"). The 14 market segments and the 7 super districts are shown in Table 5 and Figure 6, respectively.

Table 1: 14 Mode Choice Market Segments

| From/To | DC_core | DC_urban | MD_suburban | MD_urban | VA_core | VA_suburban | VA_urban |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| DC_core | 1 | 1 | 1 | 1 | 2 | 4 | 3 |
| DC_urban | 1 | 1 | 1 | 1 | 2 | 4 | 3 |
| MD_suburban | 1 | 1 | 1 | 1 | 2 | 4 | 2 |
| MD_urban | 1 | 1 | 1 | 1 | 2 | 4 | 3 |
| VA_core | 5 | 5 | 5 | 5 | 8 | 9 | 10 |
| VA_suburban | 7 | 7 | 7 | 7 | 11 | 12 | 13 |
| VA_urban | 6 | 6 | 6 | 6 | 8 | 9 | 14 |

Figure 6: Super Districts for Mode Choice Markets

The home-based trip purposes (HBW, HBO and HBS) have 4 income strata, whereas the nonhome based trip purposes (NHW and NHO) have no income stratification. Table 2 presents the mode choice constants for all purpose and mode combinations for each of the 14 market segments. Each of these constants are limited to a range of +8 to -8 . The top-level constants for income strata 1 in market segment 1 for HBW trip purpose where constrained to the allowable range, indicating a relatively close fit. However, most of the constrained markets belong to external segments and cover trips that are passing through the modeled NoVA boundary.

Table 3 presents a summary of the average values of various parameters used in the mode choice model. These averages provide a general sense of the relative magnitudes between modes. Table 4 presents the mode choice summary of trips in the NoVA modeling area by mode and trip purpose. Table 5 presents the mode choice summary for each of the 14 market segments.

Table 2: Mode Choice Constants

| SEG | MODE | HBW1 | HBW2 | HBW3 | HBW4 | HB01 | HBO2 | HBO3 | HBO4 | HBS1 | HBS2 | HBS3 | HBS4 | NHW | NHO |

### 1.5 Convergence

The TRANSIMS DTA assignments track several (convergence) gap measures, namely:

- trip-based gap - the change in trip travel times between successive iterations,
- link-based gap - the change in link travel times between successive iterations,
- toll-gap - the change in dynamic toll rates between successive iterations,
- transit-gap - the change in transit crowding penalties between successive iterations, and
- parking-gap - the change in parking capacity penalties between successive iterations.

These measures are tracked by iteration and time-period with lower values indicating greater stability in the assignment results from one iteration to the next. Figure 7, Figure 8, Figure 9, Figure 10, and Figure 11 present the trip-based gap, link-based gap, toll-gap, transit-gap and parking-gap, respectively. In each figure, diurnal distributions drawn in varying shades of gray show the gap value by time of day for each assignment iteration. The earlier iterations have large magnitudes and are shown with lighter/brighter shades of gray. The final iteration is drawn in red. These figures show that the gaps settle down as the iterations progress. Two charts are shown on each page, the chart on the top corresponds to the gap measures in the regional assignment and the chart on the bottom of each page corresponds to the NoVA assignments. Generally, the NoVA assignments achieve a tighter gap when compared to the regional assignments.

The maximum trip-gap is below 0.10 for the AM peak period for the regional run, whereas the maximum trip-gap is below 0.025 for the NoVA assignment. The link-gap is slightly higher than the trip-gap and is at approximately 0.15 at the regional assignment and at approximately 0.05 for the NoVA assignment. The toll-gaps are well under 0.01 whereas the transit-gaps are relatively unstable but at about 0.20 for the peak periods. The parking-gaps are very high for the regional run but under 0.5 for the NoVA assignment.

## 2 Validation

This chapter presents various model outputs and comparisons arranged into five sections: travel-demand, highway validation statistics, highway speed maps, highway speed profiles and transit validation reports.

### 2.1 Relevant MWCOG Model Documentation

As mentioned earlier, all of the demand inputs to the TRANSIMS model come from MWCOG Model. The MWCOG Model calibration report ${ }^{5}$ provides a detailed description of the trip generation and trip distribution steps that define the primary demand inputs.

### 2.2 Travel Demand

Table 6 presents the total number of trips by time of day, and Table 7 presents the regional trips as directly converted from the MWCOG model version 2.3.57a based on TPB/COG draft 2016 CLRP Round 9.0 land use inputs. Figure 12 to Figure 17 show the diurnal curves by trip purpose that distribute the daily trips to specific departure or arrival times in the TRANSIMS trip file. Each figure has three diurnal curves that depict the distributions of the departure times, mid-trip times and trip arrival times. The diurnal curves were generated from the COG/TPB 2007/2008 Household Travel Survey. The HBW diurnal curves show twin peaks as expected.

Table 8 shows an equivalent of Table 7 for the NoVA modeling region. Figure 18 shows the trip distance distribution by trip purpose within the region. Note that the trip distance is the straightline distance between the origin and destination zones. Table 9 summarizes the trip distribution by jurisdiction from the TRANSIMS model with adjustments based on the CTPP journey-to-work data, and Table 10 shows the distribution generated by the MWCOG model. The general jurisdictional distribution is preserved by the TRANSIMS model, but the CTPP adjustments tend to reduce intra-jurisdictional trips and trips to D.C. and increase trips from inner-jurisdictions to outer-jurisdictions.

Table 6: Travel Demand by Time of Day

| Modeled Trips | NoVA | REGION |
| :--- | :--- | :--- |
| AM Peak Period (6a-9a) | $\mathbf{1 , 6 7 9 , 1 0 6}$ | $3,268,835$ |
| Mid-Day | $2,958,217$ | $6,299,792$ |
| PM Peak Period (4p-7p) | $2,817,065$ | $5,687,109$ |
| Rest of Day | $\mathbf{1 , 2 8 6 , 6 2 6}$ | $2,656,628$ |
| Total | $\mathbf{8 , 7 4 1 , 0 1 4}$ | $\mathbf{1 7 , 9 1 2 , 3 6 4}$ |

### 2.3 Highway Validation Statistics

Table 11 presents a comparison of the 2016 assigned volumes against the 2010 TPB/COG counts in the NoVA model area. The comparison shows decent match to the counts with reasonable RMSE values. The percent difference between model volumes and counts for Freeway (6.8\%), Expressway (1.8\%) and Major arterials (2.7\%) are well within the thresholds recommended by the Travel Model Validation and Reasonableness Checking Manual ${ }^{6}$.

Table 11: Daily volumes against 2010 TPB counts

| Daily Volume by Facility Type |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Facility Type | Links | Estimate | Observed | Diff. | \% Diff. | \% RMSE | R. Sq. |
| Freeway | 58 | 3,491,747 | 3,269,511 | 222,236 | 6.8 | 18.9 | 0.894 |
| Expressway | 22 | 509,634 | 500,542 | 9,092 | 1.8 | 31.1 | 0.693 |
| Major Arterial | 110 | 2,198,959 | 2,141,318 | 57,641 | 2.7 | 30.1 | 0.674 |
| Minor Arterial | 144 | 1,369,979 | 1,183,108 | 186,871 | 15.8 | 51.2 | 0.533 |
| Collector | 100 | 646,189 | 512,160 | 134,029 | 26.2 | 59.2 | 0.773 |
| Bridge | 16 | 785,832 | 698,472 | 87,360 | 12.5 | 27.3 | 0.945 |
| Total | 450 | 9,002,340 | 8,305,111 | 697,229 | 8.4 | 33.6 | 0.934 |

Table 12 shows a comparison of the 2016 assigned volumes against a compiled list of 2015 AAWDT. The counts for the American Legion, Woodrow Wilson, and Theodore Roosevelt Bridges were obtained from Maryland SHA. The other counts were compiled from 2015 VDOT traffic volume reports and 2014 DDOT traffic volume maps. While the VDOT reports included AAWDT counts, DDOT only showed AADT. The AADT were converted to AAWDT volumes using a MWCOG conversion factor. The comparison indicates about 5 percent higher total bridge traffic than that based on 2015 AAWDT counts. It shows a decent match on the American Legion and Wilson Bridges, but somewhat higher volumes on the $14^{\text {th }}$ Street Bridge.

Table 12: Daily Potomac River crossings

| Potomac River Crossing | 2016 Estimate | 2010 AAWDT | 2015 AAWDT | 2010 \% Diff. | 2015 \% Diff. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| American Legion Bridge | 240,993 | 236,000 | 244,451 | 2.1\% | -1.4\% |
| Chain Bridge | 43,760 | 18,690 | 29,295 | 134.1\% | 49.4\% |
| Key Bridge | 39,341 | 50,174 | 50,174 | -21.6\% | -21.6\% |
| Theodore Roosevelt Bridge | 102,399 | 100,485 | 95,235 | 1.9\% | 7.5\% |
| Arlington Memorial Bridge | 52,617 | 56,595 | 53,970 | -7.0\% | -2.5\% |
| 14th St. Bridge | 228,468 | 194,000 | 200,000 | 17.8\% | 14.2\% |
| Wilson Bridge | 229,380 | 203,501 | 214,291 | 12.7\% | 7.0\% |
| Total | 936,958 | 859,445 | 887,416 | 9.0\% | 5.6\% |

### 2.4 Highway Speed Maps

The next several images present the modeled speeds against the "typical" traffic as reported by Google Maps. While Google does not publish the exact breakdown of observed speeds, an attempt was made using time-ratios to generate equivalent maps for several hours of the day in Figure 21 through Figure 28. Figure 19 and Figure 20 are conceptual and present the worst congestion for any hour during the AM and PM peak periods, respectively.

The hourly time ratio maps show congestion levels similar to those shown in the Google Typical Traffic maps for major corridors such as I-66, I-95, I-495 near Tysons Corner, and I-495 near the American Legion Bridge during both morning and afternoon peak periods.

Figure 28: Model vs. "Typical" Google Traffic @ 7:00 PM

### 2.5 Highway Speed Profiles

This section presents hourly-speed profiles from the model in comparison to the 2013 INRIX speed data at key facilities in our region as shown in Figure 29 thru Figure 41. The modeled speeds are shown in green and the INRIX speed, where available, is shown in orange. The model speed profiles at these locations generally follow the observed speed profiles.

Figure 29: Hourly Speed Profile on I-66 outside Beltway

Figure 38: Hourly Speed Profile on American Legion Bridge

Figure 39: Hourly Speed Profile on 14th Street Bridge

Figure 40: Hourly Speed Profile on Theodore Roosevelt Bridge

Figure 41: Hourly Speed Profile on Woodrow Wilson Bridge

Figure 42 depicts the volume-count comparison for several roads of the I-66 E corridor near Glebe Rd. The data were borrowed from the VDOT report titled " 2015 Mode Share Study for I66 Inside the Beltway". The model volumes matched counts very well on US-29, US-50, VA-237 and Wilson Blvd. The observed volumes on I-66 seem too low, which may indicate a data collection error.

Figure 42: Model Volumes and Counts at Glebe Rd. in I-66 E Corridor

### 2.6 Transit Validation Reports

The Table 13 and Table 14 present the 2016 estimated daily modeled ridership on Metrorail and VRE within Virginia, respectively. Table 13 compares the assignment results to the 2015 results from the last adopted TPB/COG model and the 2014 "LineLoad" data generated from WMATA mezzanine counts. Similarly, Table 14 compares the assignment results to the 2015 COG/TPB values and the 2014 VRE ridership survey. Overall, the tables indicate an acceptable match to the two comparison sources. The system-wide metro ridership estimated by the model matches the LineLoad ridership more closely than it does the COG model. The model provides the best match for the section between Ballston-MU station and Rosslyn station. The model provides decent match to the ridership of Manassas line and slightly underestimates the VRE ridership on the Fredericksburg line.

Figure 43 shows a comparison of model versus observed park and ride conditions. High parking demand is shown at major end-of-line stations such as Vienna, Wiehle-Reston and Franconia-Springfield.

Table 13: Daily Metrorail Ridership in Northern Virginia
